OmniLume

Windows Reset Backup and Restore Guide

A simple, safe checklist for preserving your project, Codex chats, skills, credentials, and cloud connections.

Read this before resetting Windows.
Do not reset the laptop until you have completed the backup checklist and opened the backup from the pendrive to verify it.

Prepared for the OmniLume project on Windows. This guide contains no passwords, access tokens, or secret values.

1. The simple answer

Your GitHub, Supabase, Vercel, and account-based ChatGPT project data are stored in the cloud. The things most at risk during a laptop reset are your local project changes that were never pushed, local Codex history/state, installed skills, local environment files, and local settings.

My recommendation: make two backups before resetting: (1) an encrypted pendrive backup, and (2) an official ChatGPT data export. Keep the pendrive backup until the new installation is working and verified.

A reset removes installed programs and local Windows data. It does not normally delete data already stored in GitHub, Supabase, Vercel, or your OpenAI account, but you must be able to sign back into the same accounts.

Your current OmniLume repository is C:\Omnilume\omnilume1. The project has an .env.local file and local Codex folders were found on this laptop, so those must be handled carefully.

2. What is cloud-saved and what is local

Item	Where it lives	After reset	What you should do
Committed OmniLume code	GitHub repository	Safe in GitHub	Still copy the project folder to preserve uncommitted work.
Supabase database and Storage	Supabase cloud project	Safe in Supabase	Keep access to the same Supabase account. Download important files separately if you need an offline copy.
Vercel deployment	Vercel cloud project	Safe in Vercel	Keep access to the same Vercel account and verify environment variables.
ChatGPT project chats/files	OpenAI account/project	Should return after same-account login	Request the official data export as an extra backup.
Codex local task history	C:\Users\tatti\.codex	May not be restored automatically	Copy the entire folder while Codex is closed, encrypted.
Installed skills	C:\Users\tatti\.codex\skills and C:\Users\tatti\.agents\skills	Removed with Windows	Copy both folders to the pendrive.
Local environment variables	C:\Omnilume\omnilume1\.env.local	Lost if not copied	Copy only into an encrypted backup; never commit it.
Git, Node.js, ChatGPT app	Installed programs	Must be reinstalled	Record versions and reinstall after reset.

3. Prepare the pendrive

Use a pendrive with enough free space. Create this folder structure on it:

```
OMNILUME_RESET_BACKUP_2026-09-24/
  01_PROJECT_COPY/
  02_CODEX_LOCAL_BACKUP_ENCRYPTED/
  03_SKILLS/
  04_CHATGPT_EXPORT/
  05_ACCOUNT_RECOVERY/
  06_RESTORE_NOTES/
```

Security rule: the folders containing .env.local, Codex authentication/session files, or browser/password exports must be inside an encrypted archive or on an encrypted pendrive. Do not leave these files as ordinary unencrypted files.

Recommended protection: enable BitLocker on the pendrive, or create an AES-256 encrypted 7-Zip archive with a strong password. Store the password somewhere separate from the pendrive.

4. Save the OmniLume project

- Close the running development server and any editor that is writing files.

- Open File Explorer and go to C:\Omnilume.

- Copy the entire folder C:\Omnilume\omnilume1 into 01_PROJECT_COPY.

- Make sure hidden files are visible so .env.local is included.

- If the copy is too large, node_modules and .next can be skipped. They can be recreated later. Keep src, public, supabase, tests, package.json, package-lock.json, README files, roadmap files, .git, and .env.local.

- Never upload .env.local to GitHub. Keep it only in the encrypted backup.

The current GitHub commit already contains the committed Actions 05-10 work. A full project copy is still necessary because local uncommitted files are not guaranteed to be on GitHub.

5. Save Codex chats and local Codex data

The Codex application on this laptop has local state/history files under C:\Users\tatti\.codex, including local history databases. To preserve the local copy:

- Quit the Codex desktop app completely. Check the Windows taskbar and Task Manager so no Codex process is still running.

- Copy the entire folder C:\Users\tatti\.codex into 02_CODEX_LOCAL_BACKUP_ENCRYPTED.

- Also copy C:\Users\tatti\AppData\Roaming\Codex and C:\Users\tatti\AppData\Local\Codex into that encrypted backup if you want to preserve local app settings and cache.

- Do not copy these folders to GitHub or share them with anyone.

- Do not restore auth.json or cap_sid as a first step after reinstall. Log in again instead.

Important: this local copy is a safety archive. OpenAI account chats and project files should be accessed again by signing into the same account, but direct restoration of internal Codex databases is version-dependent. Keep the old archive until the new installation is verified.

6. Save all installed skills

Copy both skill locations into 03_SKILLS:

```
C:\Users\tatti\.codex\skills
C:\Users\tatti\.agents\skills
```

The second folder contains many of the installed development skills, including prompt-master and other coding skills. Copy folders, not only shortcuts.

After the reset, skills can be restored by copying them back to the same locations while Codex is closed, or reinstalled using Codex's skill/plugin tools.

7. Request the official ChatGPT export

- Open ChatGPT and sign into the exact account you use for your projects and Codex.

- Open Profile, then Settings, then Data Controls.

- Choose Export Data and confirm the request.

- Wait for the email or message. It can take up to seven days.

- Download the ZIP using the same signed-in account. The download link expires after 24 hours.

- Copy the ZIP into 04_CHATGPT_EXPORT.

- Open the ZIP and verify that the conversations you care about are present before resetting.

Official instructions: https://help.openai.com/en/articles/7260999-how-do-i-export-my-chat-history-and-data

8. Save account recovery information

In 05_ACCOUNT_RECOVERY, save a plain text checklist without passwords or tokens:

- OpenAI account email and the sign-in method used.

- GitHub account name and repository URL.

- Supabase project name and project reference: cqmqliqfrasaxzuyeshc.

- Vercel account and project name.

- The email addresses that receive verification messages.

- Where your two-factor authentication device and recovery codes are stored.

Do not put passwords, access tokens, Supabase service-role keys, GitHub tokens, browser cookies, or Codex auth files in this plain text note.

9. Optional cloud-data safety copies

- Supabase database and Storage objects live in the cloud and should survive the laptop reset. If you need disaster recovery, use Supabase's own backup/export features or download irreplaceable Storage files separately.

- Your existing room media is not stored in GitHub. Download any irreplaceable local media from Supabase Storage if you need an offline copy.

- Vercel environment variables remain in Vercel, but local .env.local must still be backed up securely or recreated.

10. Verify the pendrive backup before resetting

Do not skip this. A backup is useful only if it can be opened.

- Open 01_PROJECT_COPY and confirm you can see src, supabase, tests, package.json, package-lock.json, README.md, and the roadmap files.

- Confirm the encrypted backup has the .codex and skill folders. Do not open or display auth.json in a public place.

- Confirm the ChatGPT export ZIP is present and opens.

- Confirm .env.local is present only inside the encrypted project backup.

- Safely eject the pendrive and reconnect it once to confirm it is readable.

- Keep a second copy on another encrypted drive or trusted encrypted cloud storage if possible.

Only after these checks pass should you reset Windows.

11. After the Windows reset: install the software

- Run Windows Update first.

- Install a browser such as Chrome, Edge, or Brave.

- Install Git for Windows.

- Install the current Node.js LTS release.

- Install the ChatGPT/Codex desktop app.

- Install 7-Zip if you used an encrypted 7-Zip backup.

- Optionally install GitHub CLI. It is not required for Codex GitHub integration, but it is useful for gh commands.

You do not need to back up the Git or Node.js program folders. Reinstalling them is safer than copying old program files.

12. Sign in again

- Sign into ChatGPT/Codex using the same OpenAI account. Open the OmniLume project and check that the project chats and files are visible.

- Sign into GitHub using the same GitHub account.

- Sign into Supabase using the account that owns omnilume1’s Project.

- Sign into Vercel using the account connected to the OmniLume deployment.

- Complete two-factor authentication using your normal authenticator or recovery codes.

- Do not copy old browser cookies or old Codex auth tokens into the new installation.

13. Restore the project

Use GitHub as the clean source for committed code:

```
git clone https://github.com/omnilume1/omnilume1-project.git
cd omnilume1-project
npm ci
```

Then restore the encrypted local files you intentionally kept:

- Copy .env.local from the encrypted backup into the project root. Never commit it.

- Copy the Action 08 diagnostic SQL back only if you want it locally and it is not already in GitHub.

- Do not restore Supabase .temp files; they are local CLI metadata and will be regenerated.

- Do not copy node_modules or .next from the old computer. Run npm ci and rebuild instead.

Run the basic checks:

```
node --version
npm --version
git --version
npm run lint
npx tsc --noEmit
npm run build
```

14. Restore the skills

Close Codex, then copy the backed-up skill folders back to the same locations:

```
C:\Users\tatti\.codex\skills
C:\Users\tatti\.agents\skills
```

Open Codex again and verify that prompt-master and your other skills appear. If a skill does not appear, reinstall it through Codex instead of copying authentication/session files.

15. Reconnect Supabase CLI only if needed

```
npx supabase login
npx supabase link --project-ref cqmqliqfrasaxzuyeshc
npx supabase migration list
```

Run these only after the project is restored and only when Codex or your workflow needs CLI access. Never paste passwords or tokens into chat.

16. Final restore checklist

Check	Expected result
OpenAI login	Same account; OmniLume project and important chats are visible.
ChatGPT export	ZIP was downloaded and verified.
GitHub	Repository clones successfully and main branch is present.
Project	npm ci completes; lint, TypeScript, and build pass.
Environment	.env.local is restored privately and never committed.
Skills	prompt-master and other skills are visible after restarting Codex.
Supabase	Correct project reference cqmqliqfrasaxzuyeshc is linked.
Vercel	Deployment and environment settings remain available in the dashboard.
USB backup	Kept safely until the new setup works for several days.

17. If something is missing

- If project chats are missing, confirm that you signed into the same OpenAI account and check the project sidebar and chat search.

- If a ChatGPT conversation is missing, inspect the official export ZIP before deleting the old backup.

- If local Codex task history does not reappear, keep the old .codex archive. Do not overwrite the new installation with old auth files. The archive can be retained for later support or migration help.

- If local environment variables are missing, recreate them from the encrypted backup or the Vercel/Supabase dashboards.

- If Supabase CLI authentication fails, run npx supabase login again and verify the project reference.

- If GitHub authentication fails, sign in again through Git or GitHub CLI. Do not copy old credential files.

Keep the old laptop backup until all of these work: project runs locally, Codex opens, important chats are found, skills load, Supabase links to the correct project, and the site can be built.

This PDF is a backup and restore checklist. It does not contain account credentials and should not be used as a replacement for your encrypted secrets backup.

One-page action list

Before reset

- Request and verify the ChatGPT data export.
- Copy C:\Omnilume\omnilume1 to the pendrive.
- Copy C:\Users\tatti\.codex to the encrypted backup.
- Copy C:\Users\tatti\.codex\skills and C:\Users\tatti\.agents\skills.
- Protect .env.local, auth/session files, and any credentials with encryption.
- Open the backup and verify it before resetting.

After reset

- Install Windows updates, Git, Node.js, ChatGPT/Codex, browser, and 7-Zip.
- Sign into the same OpenAI, GitHub, Supabase, and Vercel accounts.
- Clone the GitHub repository and run npm ci.
- Restore .env.local securely.
- Restore skills; do not restore old authentication tokens.
- Run lint, TypeScript, and build checks.
- Keep the old backup until everything works.

Bottom line: GitHub and the cloud services preserve the committed and hosted parts. The pendrive must preserve the local project copy, uncommitted work, Codex local history archive, skills, ChatGPT export, and encrypted environment files.
